

CTC-025 JFET ESD

Introduction:

The objective of this document is to provide information about the various types of ESD testing and methods, the kind of damage that ESD can cause to equipment, and the results of the ESD testing on InterFET products.

What is ESD?

We are all familiar with the concept of electrostatic discharge, or ESD, because we often experience it when touching a metal doorknob after walking across a carpeted floor. It can give us quite a jolt, especially during winter when relative humidity is often low.

Electrostatic charge is defined as electric charge at rest. Electrostatic discharge is the spontaneous transfer of that charge. That charge usually travels as a spark between two bodies as they come close to each other, or touch. Electric charge can build up on even an insulative material, one that prevents or limits the flow of electrons.

ESD can create havoc in electronic components and systems. It can damage an expensive component that renders a complicated and expensive system useless. ESD comes with a cost; ESD damage during assembly affects profitability as it impacts production yields, manufacturing costs, product quality and reliability. As electronic devices get smaller and faster, sensitivity to ESD increases.

Types of damage from ESD

1. Catastrophic damage that renders a device inoperable. This can be a result of damage to a semiconductor junction or connecting metallization.
2. Latent damage of a device can happen in which a device or sensitive circuit fails at some point in the future. It's important to note that static discharge has a cumulative effect.
3. Sensitive components or integrated circuits can be damaged when handled by humans, during assembling in an automated process, or due to user interactions in the end application. ESD damage to ICs can occur at any time, from assembly to board level soldering and user interactions. Significant voltage and current spikes can occur in the end user environment from ESD event that results in system failure.

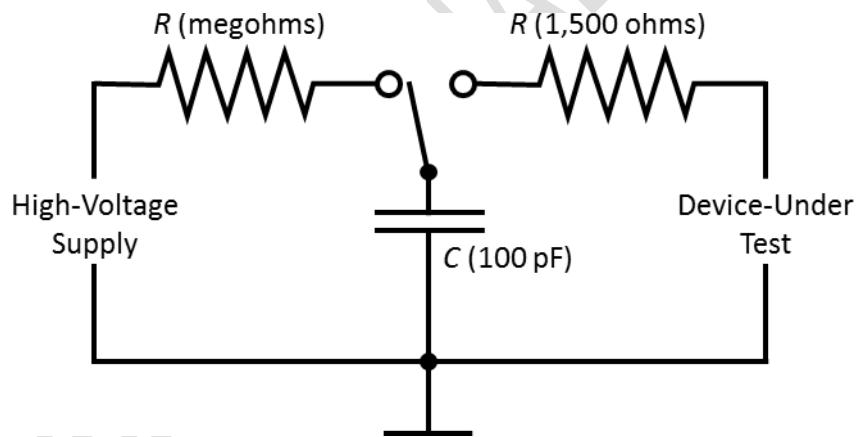

ESD Classifications and Measurements

ESD events are simulated or characterized by four different models:

- HBM: human body model
- MM: Machine Model
- CDM: charged device model
- IEC 61000-4-2 System level immunity standard by the International Electrotechnical Commission

Human Body Model (HBM)

The HBM is the oldest model and was originally developed for investigating explosions of gas fixtures and mines. This model is intended to emulate ESD events caused by human handling and is perhaps the most familiar or common. This is the direct transfer of electrostatic charge from a human body to an ESD sensitive device (ESDS). An individual can pick up a charge simply from walking across the floor, and subsequent contact, or proximity, allows discharge of energy. The HBM is referenced in ANSI/ESDA/JEDEC JS-001 “electrostatic discharge sensitivity testing human body model component level” and is represented by the circuit below:

The above capacitor is charged by a high voltage supply through a high megaohm resistor and then switched so the energy is discharged through a 1500 ohm series resistor and the component to ground potential.

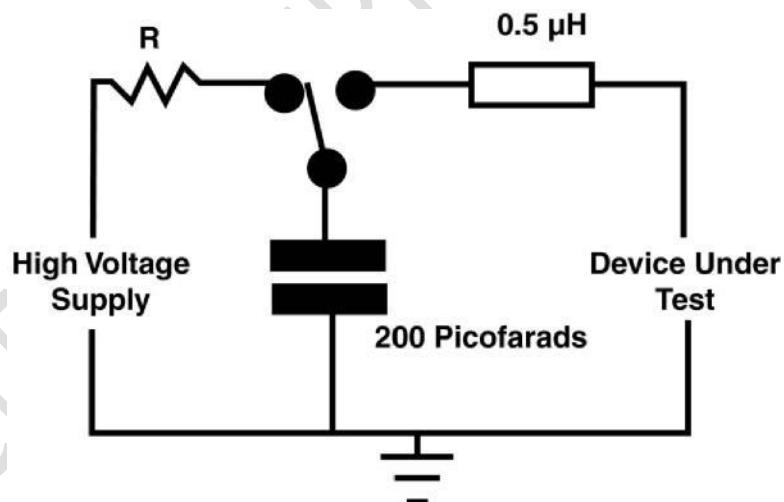

This model addresses handling issues of a part. It is designed to represent the discharge from a person's finger to the device. A failed device is one that does not meet the datasheet parameters using parametric and functional tests.

The HBM method includes a classification system for defining component sensitivity. This allows comparison of different components according to their sensitivity:

Class	Voltage Range (V)
0Z	< 50
0A	50 to < 125
0B	125 to < 250
1A	250 to < 500
1B	500 to < 1000
1C	1000 to < 2000
2	2000 to < 4000
3A	4000 to < 8000
3B	>= 8000

Machine Model (MM)

The machine model originated in Japan to create a worst-case version of the human body model and it was intended to emulate ESD events caused by automated handling. This is simulated with a 200 pF capacitor discharged directly into a component with without the 1500 ohm resister used in the HBM. Series inductance (shown below) is the dominant parasitic element that shapes the oscillating waveform of the MM. Since the inductance has not been uniformly established, the voltage the device can withstand might differ by a factor between two and five in different test setups. For this reason, JEDEC and ESDA recommends qualifying components using the HBM or the CDM described later.

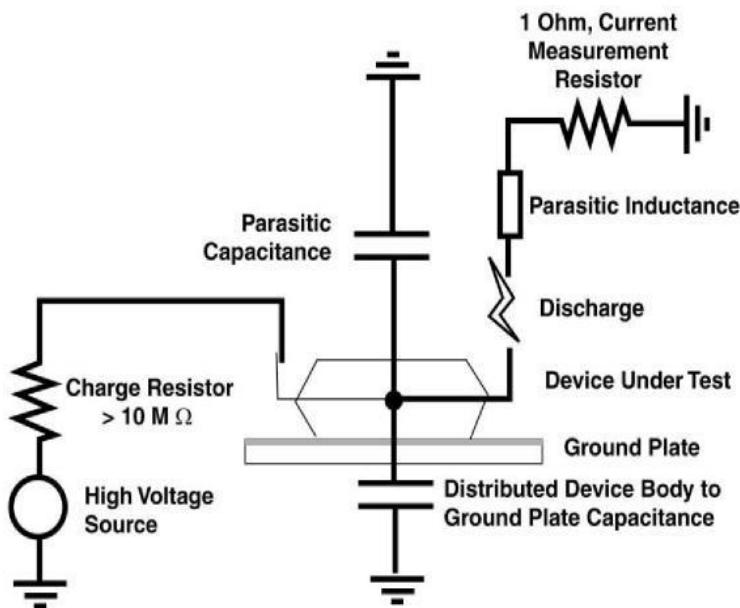

Class	Voltage Range (V)
M1	< 100
M2	100 to < 200
M3	200 to < 400
M4	>= 400

Charged Device Model (CDM)

The transfer from an ESDS device to a conductive device (at a lower potential) is also an ESD event that can be more damaging than the HBM event. The duration of discharge in the case of the CDM is rather short but the peak current can reach several tens of amperes. This can result in the breakdown of dielectric and do other harm. The CDM model is intended emulate ESD events caused by products charging or discharging

The standard for device testing is specified in JS-002 and is represented below:

In this test, the device under test (DUT) is placed on a field plate with all leads pointing up, thus all pins are treated equally. They are discharged after positive and negative charging.

Both HDM and CDM classifications are helpful as they allow objective comparison and groupings of ESD sensitive components; the designer has an indication of the level of ESD protection necessary to support each component.

Class	Voltage Range (V)
COA	< 125
COB	125 to < 250
C1	250 to < 500
C2A	500 to < 750
C2B	750 to < 1000
C3	>= 1000

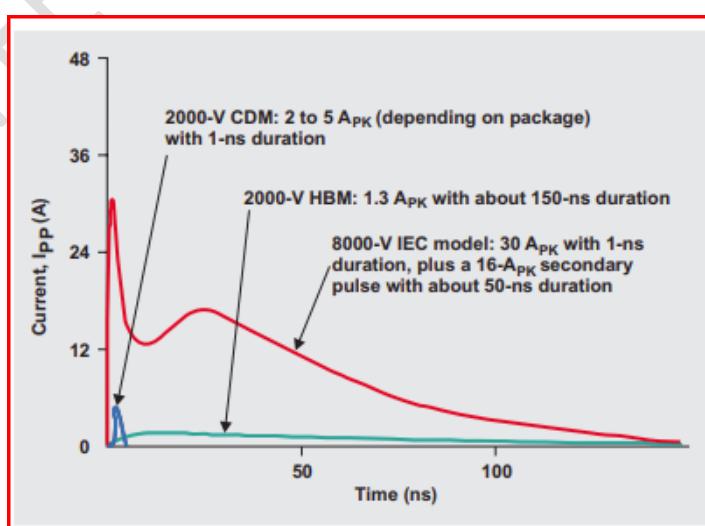

IEC 61000-4-2

The purpose of the IEC 61000-4-2 standard is to characterize system-level threats. The three models mentioned above allows a circuit designer or component engineer to compare components, with a general understanding of the level of ESD sensitivity for a given part. They serve as guides, not necessarily as absolutes. In the end user application, the levels of both voltages and currents from an ESD strike can be much greater at the system level. The IEC standard is intended to simulate ESD events at the system level in the real world. This standard covers two discharge mechanisms: Contact discharge (where two surfaces at different potential physically touch) and air gap discharge. The range of test levels for both contact discharge and air gap discharge are shown below:

Contact Discharge	Test Voltage (kV)	Air Discharge	Test Voltage (kV)
1	2	1	2
2	4	2	4
3	6	3	8
4	8	4	15

For purpose of comparison of component level with system level models:

Model	HBM	MM	CDM	IEC
Definition	Human body discharging static	Discharge of accumulated static in assembly	Charged device being grounded	Real world system level threats to ESD
Test levels (voltage)	500 - 2000 V	100 -200 V	250 - 2000 V	2000 -15000 V
Pulse Width (ns) approx.	150	80	1	150
Peak Current at 2kV applied (A)	1.33	-	5	7.5
Rise Time	25 ns	-	< 400 ps	< 1 ns
Number of strikes	2	2	2	20

How well do JFETs Handle ESD?

Because JFETs are [voltage controlled](#) devices, as well as the lack of any oxidizing layer, and their simple construction, JFETs are much more resistant to ESD than MOSFETs. A positive ESD event on a [JFET](#) is likely to run the JFET in forward bias mode, unlikely to damage the JFET. In the case of a reverse bias event, this will likely surpass the breakdown voltage, however if the current is not too large, damage to the JFET is not incurred.

Testing results for all InterFET JFET's are listed in the tables below:

InterFET INTERNAL USE ONLY

InterFET ESD Results
